

Module outline

- Anatomy
- Myocytes
- **Cardiac cycle**
- Haemodynamics & blood pressure
- Coronary circulation
- Capillaries

Cardiac cycle

Frank-Starling law of the heart

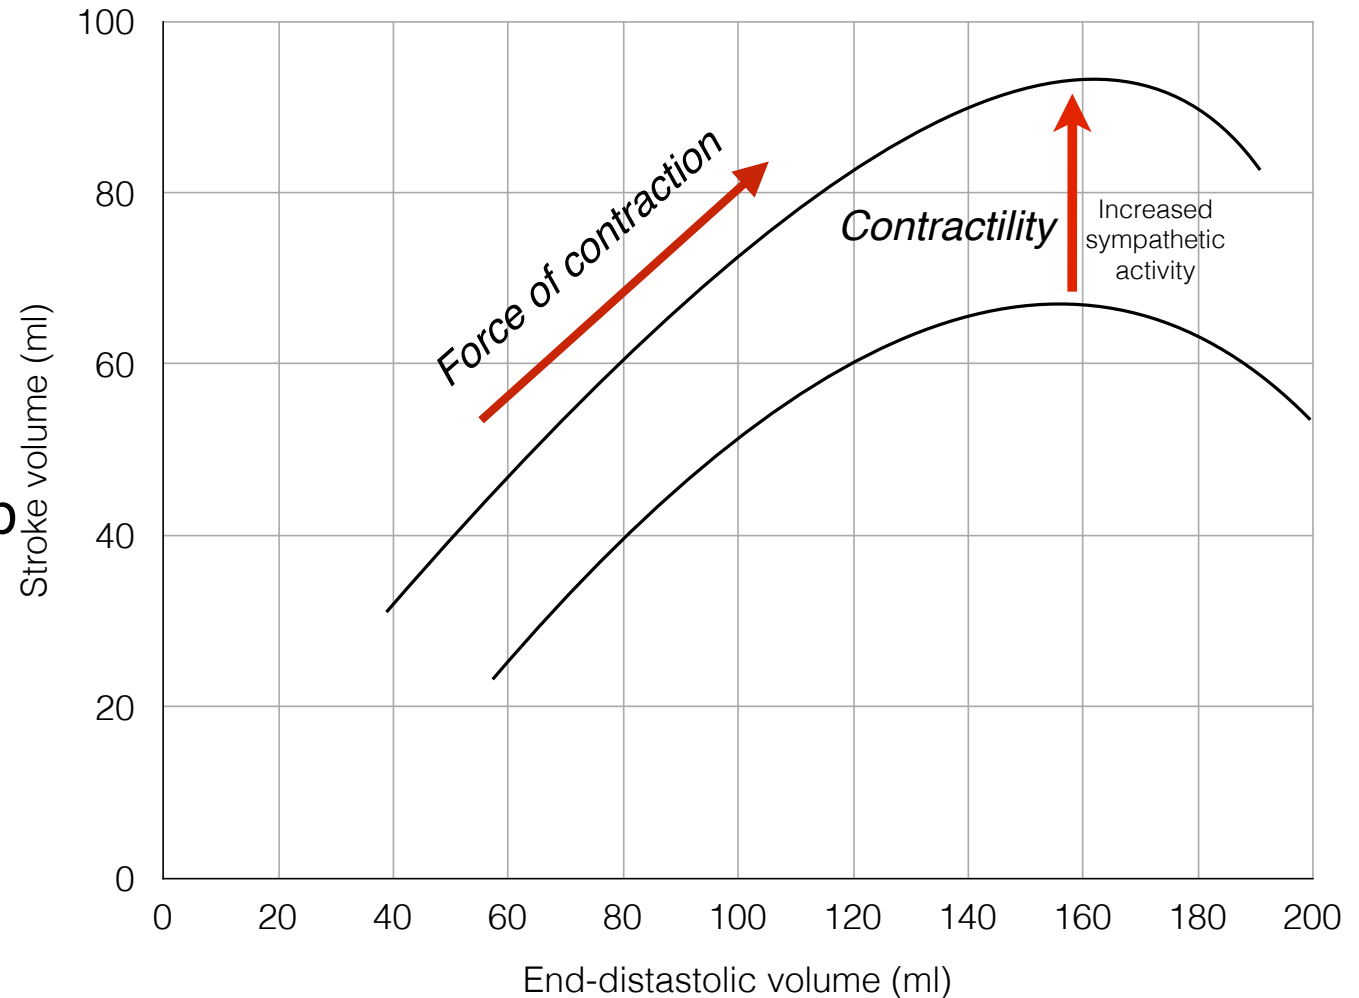

- Preload/EDV determines SV
- Length tension relationship = EDV
- Filament overlap
- Symp \uparrow SV for any given EDV

Frank-Starling law of the heart

Factors affecting EDV:

- Venous tone
- Blood volume
- Skeletal muscle pump
- Respiratory pump
- Posture

Heart failure

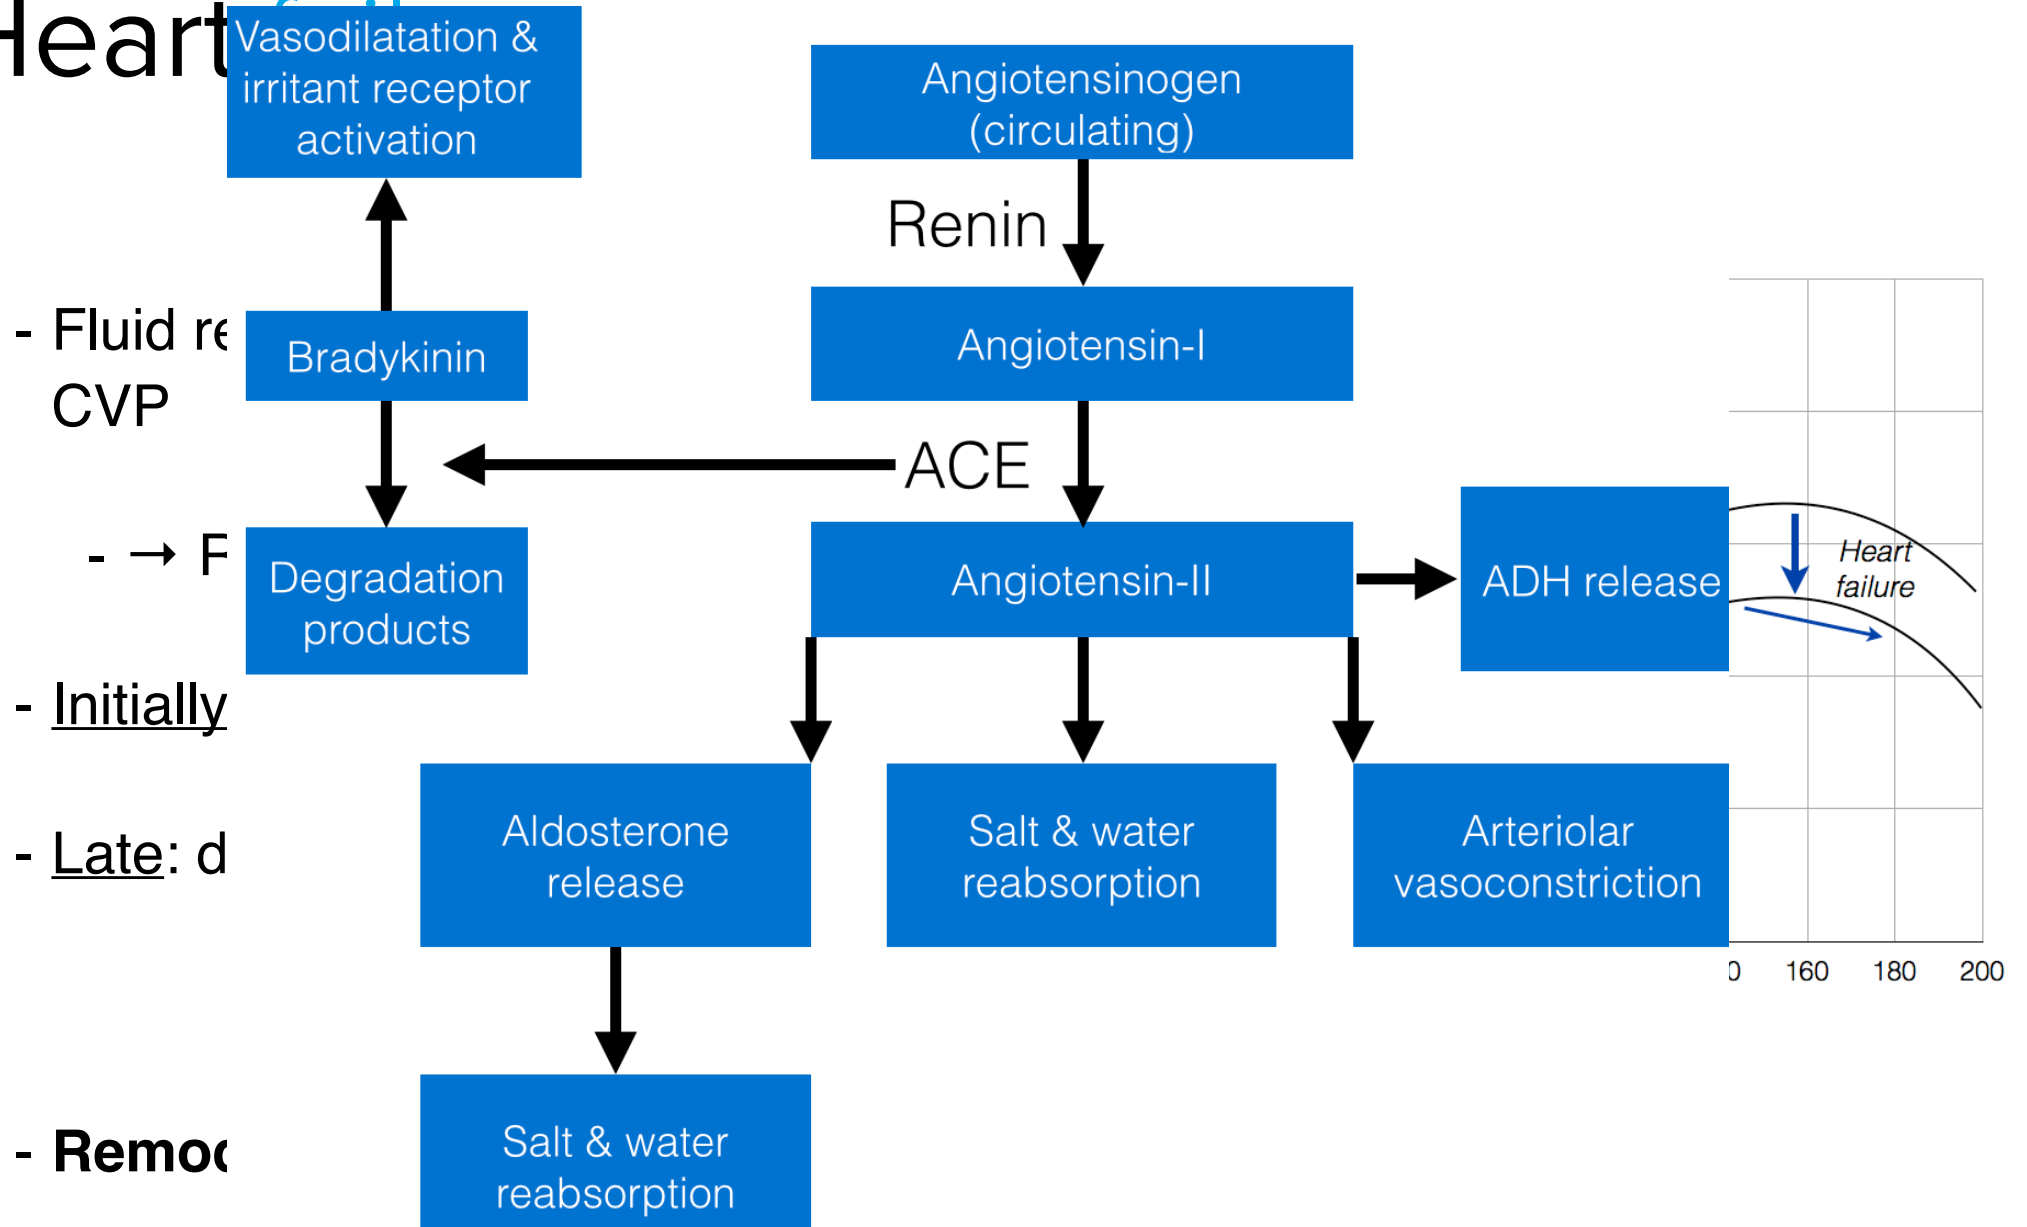

- = Cannot meet metabolic demand (at normal CVP)
- Causes of heart failure:
 - Ischaemic heart disease
 - Hypertension
 - Valvular disease

Heart failure

Heart Failure

Heart failure

RAAS: (↓renal perfusion)

- Fluid & Na⁺ retention
- Ang-II → Constriction

Sympathetic activation

- A → Renin (β1)
- ↑ Contractility
- ↑ HR (inc. ↓ Vagus)
- NA → Vasoconstriction

∴ ↑ AFTERLOAD* → ↑ ENERGY & ↓

*Afterload = total peripheral resistance

Heart failure

Right-sided heart failure

Raised jugular venous pressure

Hepatomegaly

Peripheral oedema

Ascites

Fatigue

Left-sided cardiac failure

Pulmonary oedema

Peripheral hypoperfusion

Orthopnoea

Paroxysmal nocturnal dyspnoea

Cough & wheeze

Key points

- **Pacemaker cells** have a depolarising pre-potential due to high sodium permeability
- **End-diastolic volume** (pre-load) determines force of contraction by controlling myocyte length
- **Sympathetics** increase SAN rate, reduce AVN delay and increase ventricular contractility
- Heart failure causes right- & down-wards shift on **Frank-Starling curve**
